

The annotation feature allows the user to attach metadata, either in the form of strings to be tested for in formatting commands, or in the form of strings to be printed as-is. This example demonstrates all aspects of the annotation feature:

- Metadata attaching to fields, items in a list or parts of an item in a list (e.g. name parts)
- Literal annotations where the annotation is a string to be printed rather than used as a metadata test for other formatting.
- Multiple named annotations for the same data field.
- The “default” name for annotations with no explicit name.
