

IMPLEMENTATION NOTES AND MANIFEST

MICHAEL SHARPE

1. INTRODUCTION

1.1. Issues using rtxmi from the txfonts collection. This font supplies all the non-alphabetic glyphs (ie, everything except A–Z and a–z) in the OML encoding, but, not using the same names as in `oml.etc`. To get around this, we must base fontinst constructions not on its afm, but instead, use what may be thought of as an anonymous metric file constructed from its tfm via

```
tftopl -charcode-format=octal rtxmi rtxmi
```

so that `rtxmi.pl` identifies slots only by octal codes, not names, and identifies the encoding as `FONTSPECIFIC`, which usually means “as specified in the header of `rtxmi.pfb`.” By including in the fontinst driver script a line

```
\declareencoding{FONTSPECIFIC}{oml}
```

we force the slots in `rtxmi` to be interpreted using the names in `oml.etc` so that, at the end, we have no problems using `oml` as the encoding for composite fonts built from `rtxmi`.

The original version of txfonts made use of whatever Times font was installed in TeX Live, and as a non-free font, it was not available for modification. In this updated version, we use instead the alphabetic glyphs from TeXGyreTermes or LinLibertine, each of which presents no licensing issues. This allows us to make optical sizes of the math italic and symbol fonts, with a boost to the appearance and readability of subscripts, sub-subscripts and superscripts. (Unfortunately the STIX math italic letters are much heavier than Times, by nearly 15% in stem thickness of uppercase letters, and do not make a good substitute.)

2. MAKING 7pt AND 5pt VERSIONS

- The strokes in 7pt type are (mostly) relatively thicker than those in the 10pt type;
- the side-bearings are a bit bigger in 7pt type—about 30em on the left and about 20em on the right;
- the 7pt glyphs are (relatively) wider than those in the 10pt size.

What we seek is a way to transform 10pt glyphs into 7pt glyphs using some simple FontForge transformations. The following seems to work fairly well:

- Open the .pfb in FontForge—you need to have the .afm or the .pfm in the same folder to get the correct metrics;
- select all glyphs (CRTL-A) and select from the Element menu, Style/Change glyph—this brings up a window with 3 tabs, the first named Stems, where you should select Separate ratios for horizontal and vertical stems and check the box marked Activate diagonal stem processing, then enter 100%+o for Horizontal Stems and 108%+o for Vertical Stems;
- press OK, which should thicken all non-horizontal stems in the font, but most likely cause some validation issues which must be dealt with before proceeding;
- select the menu item Element/Validate/Validate to check for problems—there may be many, and the simplest way to proceed is to right click on one of them and choose the contextual menu items at the bottom of the list, one by one;

- some glyphs may require manual adjustments to smaller stems to make them more uniform—the glyphs M, W, V needed help in my case;
- assuming your font validates, the next step is the menu item Element/Style/Change Glyph, and in this round we choose the second tab, named Horizontal, selecting Uniform scaling..., entering 107%+o for the Counter Size, then press OK;
- validate the transformed font, just as described above, and, after it validates, select the menu item File/Generate Fonts to export the result to a new pfb/afm combination, say xxx7, from which you may generate a tfm using
`afm2tfm xxx7 -0 xxx7`

Iterating the same sequence of operations starting from `xxx7.sfd` will produce fonts and metric files suitable for 5pt.

3. CONVERTING LIBERTINE

Making Libertine text italic and Greek glyphs into math italic and Greek glyphs requires some preparation. In a number of cases, we want to substitute (virtually) Greek glyphs from Libertine into a math italic (or mia) font. As the Greek glyphs are not encoded, we proceed as follows:

```
afm2tfm fxlri -T libertinealt.enc -v fxlri-alt rfxlri-alt
```

which creates `rfxlri-alt.tfm` and `fxlri-alt.vpl` containing the Greek glyphs in the order they should be for TeX, and which outputs, for the map file, the line

```
rfxlri-alt LinLibertineI " LibertineAltEncoding ReEncodeFont " <libertinealt.enc
```

and then

```
tftopl rfxlri-alt rfxlri-alt
```

makes `rfxlri-alt.pl`, from which fontinst may construct `rfxlri-altmtx`. The other `-alt` versions were constructed in a similar manner.

There is a tfm in the TeXLive distribution named `fxlri-8r.tfm` which provides the `fxlri` in 8r encoding, which of course includes all the Roman letters. To get an equivalent for 7pt and 5pt requires us to open the original `fxlri.pfb,afm` in FontForge and subject them to the two stages of thickening and extending described above. The result should be

```
fxlri-7letters.{pfb,afm}
fxlri-5letters.{pfb,afm}
fxlzi-7letters.{pfb,afm}
fxlzi-5letters.{pfb,afm}
```

from which we produce four corresponding tfm files using, eg,

```
afm2tfm fxlri-7letters
```

which must be referenced in the `ntx.map` file with four lines like

```
fxlri-7letters LinLibertineI7 <fxlri-7letters.pfb
```

The same fonts are now used with a different encoding to tease out Greek letters and some other unencoded glyphs like alternate versions of J, g, v and y. Note that these are not available in the semibold font—we have to resort to other tricks for that. First, run four commands similar to

```
afm2tfm fxlri-7letters -T libertinealt.enc -v fxlri-7alt
```

which produces `fxlri-7alt.tfm` (must be referenced in the map file) and `fxlri-7alt.vpl` which will be used only in the creation of the virtual font `nxmlm7.tfm,vf` by fontinst.

3.1. Making bold J and bold v. These glyphs are missing in `fxlzi.pfb`, the semibold Linux Libertine that matched bold TX better than bold Linux Libertine, which seems to be a quite different font, more like bold Palatino. So, we take the `Jcircumflex` glyph and remove the circumflex to make a J and take the `v.alt` glyph from `fxlri` and embolden it by `40em` to make a bold version of the math italic v. From this next font `fxlzi-jv.pfb` with just two glyphs, we make a `tfm` with

```
afm2tfm fxlzi-jv
```

which makes `fxlzi-jv.tfm`, a reference to which we must add to a `.map` file with

```
fxlzi-jv fxlzi-Jv <fxlzi-jv.pfb
```

assuming of course that in the course of making your font, you had given the internal name also as `fxlzi-Jv`. Finally, we have to make versions that work as `7pt` and `5pt` fonts using the same methods as described above, resulting in `fxlzi-jz{5,7}.{pfb,afm,tfm}` for our later use. For each `afm`, make a `tfm` using lines like

```
afm2tfm fxlzi-jv
```

and then, for each `.tfm`, make a `.pl` with

```
tftopl fxlzi-jv fxlzi-jv
```

and so on.

4. ISSUES WITH MATH ITALIC V AND W

Linux Libertine contains a glyph named `v.alt` that is distinct from Greek `\nu`, and that glyph is used as the default math italic v. It is certainly problematic—it just doesn't fit in with other Libertine glyphs, though it is surely distinctive. The recent versions of newtx offer the option `libalvw` which provides substitute glyphs for math italic v and w (based on Linux Libertine upsilon, with some serious modifications) so that one has glyphs that appear to be in the same family, with v distinct from `\nu`.

After constructing the glyphs using FontForge, the same procedure described above for `7pt` and `5pt` sizes was applied, and new virtual fonts constructed.

5. FILES IN THE DISTRIBUTION

This list is current as of June 13, 2012. The following abbreviations are used in the remarks:

FF means FontForge;

EW means “thicken vertical stems by 8% and extend width by a further 7% using FontForge”;

EW² means “perform EW twice”.

PostScript font files:

Size	Date	File	Remarks
706160	May 19	13:58 fxlri-5letters.pfb	EW ² applied to fxlri
